

Lasso for Hawkes process

April 19, 2019

1 Notation and definition (may be imprecise)

- M , total number of neurons
- K , number of bins
- δ , size
- N_{tot} , total number of spikes
- $\mathbb{I}_k =](k-1)\delta, k\delta] = ((k-1)\delta, k\delta], \forall k \in \llbracket 1, K \rrbracket$
- for any $\theta, k \in \llbracket 1, K \rrbracket$, $\theta + \mathbb{I}_k$ is an interval such that
$$\theta + \mathbb{I}_k = (\theta + \mathbb{I}_k) =]\theta + (k-1)\delta, \theta + k\delta] = (\theta + (k-1)\delta, \theta + k\delta]$$
- for any $\theta, k \in \llbracket 1, K \rrbracket$, $\theta - \mathbb{I}_k$ is an interval such that
$$\theta - \mathbb{I}_k = (\theta - \mathbb{I}_k) = [\theta - k\delta, \theta - (k-1)\delta[= [\theta - k\delta, \theta - (k-1)\delta]$$
- A is the scope, such that $A = K\delta$ and a maximum length. If the distance between two spikes is strictly greater than A , they don't influence each other
- T_{\min} is the beginning of the study time interval
- T^{\max} is the end of the study time interval
- $Int(x) = \lfloor x \rfloor$ represents the integer part of x
- $\lambda^{(r)}$ is the functional intensity of neuron r , function depending on time
- $\mu^{(r)}$ is the spontaneous part of $\lambda^{(r)}$
- $\mathcal{N}^{(l)}$ is the set of spike values of neuron l
- $N_{t-\mathbb{I}_k}^{(l)} = N_{[t-k\delta, t-(k-1)\delta[}^{(l)}$ represents the number of spikes θ of $\mathcal{N}^{(l)}$ such that

$$\theta \in (t - \mathbb{I}_k) = [t - k\delta, t - (k-1)\delta[$$

$$N_{t-\mathbb{I}_k}^{(l)} = N_{[t-k\delta, t-(k-1)\delta[}^{(l)} = \sum_{\substack{\theta < t, \\ \theta \in \mathcal{N}^{(l)}}} \mathbb{1}_{\mathbb{I}_k}(t - \theta) \forall t$$

2 Problem

We want to solve several minimization problems

$$\min_{a_r \in \mathbb{R}^{(1+MK)}} \frac{1}{2} a_r^t \mathbf{G} a_r - b_r^t a_r + d_r^t |a_r| \quad (\mathcal{P}_{min}^{(r)})$$

where $|v|$ is a vector such that $|v|_i = |v_i| \forall i$.

b and d are matrices of size $(1 + MK)$ -by- M , so, for any r , $b^{(r)}$ and $d^{(r)}$ are vectors of $\mathbb{R}^{(1+MK)}$ and are the r th column of b and d , respectively.

In the following, We use the class *DataSpike*. A *DataSpike* instance has two public attributes:

- *_T*: an array of double values containing all spike values independently of the neuron numbers. Values are sorted. *_T* has only one row.
- *_neur*: an array of integer values of the same size of *_T* containing the neuron numbers.

In the algorithms, an instance of the class *DataSpike* is replaced by a matrix of double values with two rows.

3 Auxiliary functions

We define the following variables

- α is the first index of T such that $T[\alpha] > T_{\min}$
- β is the last index of T such that $T[\beta] \leq T^{\max}$
- *depart* is the first index of T such that $T[\text{depart}] > T_{\min} - A$
- *departbis* is the last index of T such that $T[\text{departbis}] \leq T^{\max} - A$

α and β are defined using *get_low_index* function.

- *get_low_index* function works as follows:

$\text{get_low_index}(x, T) = \gamma$ where γ is the first index of T such that $T[\gamma] > x$

- *get_k* function works as follows:

$$\text{get_k}(x, \delta) = \begin{cases} k = \text{Int}(\frac{x}{\delta}) + 1 = \lfloor \frac{x}{\delta} \rfloor + 1 & \text{if } x > k\delta, \\ k = \text{Int}(\frac{x}{\delta}) = \lfloor \frac{x}{\delta} \rfloor & \text{if } x \equiv k\delta \end{cases}$$

or $\text{get_k}(x, \delta) = k \geq 1$ such that $x \in \mathbb{I}_k =](k-1)\delta, k\delta]$

For example $\text{get_k}(1.5\delta, \delta) = 2$ and $\text{get_k}(\delta, \delta) = 1$.

Algorithm 1 *get_low_index* function

Usage: get_low_index(x, T)

Description: Computation of ind, the first index in T such that $T[ind] > x$.
T is supposed to be sorted in ascending order. Possible values of ind are between 1 and (T.size()+1) (included). If get_low_index==1, it means that all values of T satisfy $T > x$. If get_low_index==(T.size()+1), it means that all values of T satisfy $T \leq x$. (To be improved!)

Input: x; scalar value

Input: T; array of spike times

Output: ind - integer. If there is no index satisfying the condition, the size of T + 1 is returned.

```
1: ind ← 1
2: n ← length(T)
3: while (ind < (n+1)) do
4:   if (T[ind] ≤ x) then
5:     ind ← ind+1
6:   else
7:     break
8: return ind
```

Algorithm 2 *get_k* function

Usage: get_k(x, delta, eps)

Description: Computation of k such that $x \in \mathbb{I}_k =](k-1)\delta, k\delta]$

Input: x; scalar value

Input: delta; δ

Input: eps; for numerical precision, default value 1e-12 (optional argument)

Output: k; integer

```
1: k ← floor(x/delta) + 1
2: if |k * delta - x| < eps then
3:   return k
4: if |(k-1) * delta - x| < eps then
5:   return k-1
6: return k
```

4 Computation of b

$$b^{(r)} = \begin{pmatrix} \#^{(r)} = \#\{T : T_{\min} < T \leq T^{\max}, T \in \mathcal{N}^{(r)}\} \\ \dots \\ \int_{T_{\min}}^{T^{\max}} N_{[t-k\delta, t-(k-1)\delta]}^{(l)} dN_t^{(r)} = \int_{T_{\min}}^{T^{\max}} N_{t-\mathbb{I}_k}^{(l)} dN_t^{(r)} = \sum_{\substack{T_{\min} < T \leq T^{\max}, \\ T \in \mathcal{N}^{(r)}}} \sum_{\substack{\theta < T, \\ \theta \in N^{(l)}}} \mathbb{1}_{\mathbb{I}_k}(T - \theta) \\ \dots \end{pmatrix}$$

For b we use also the notation

$$\mu_1^{(r)} = \left(\begin{array}{c} \dots \\ \int_{T_{\min}}^{T_{\max}} N_{[t-k\delta, t-(k-1)\delta[}^{(l)} dN_t^{(r)} = \int_{T_{\min}}^{T_{\max}} N_{t-\mathbb{I}_k}^{(l)} dN_t^{(r)} \\ \dots \end{array} \right)$$

WARNING

- In what follows, numbering starts at 1 (think Matlab/Octave and R) and you should be careful when it differs.
- In what follows
the loop $for(i = \alpha : \beta)$ is empty if $\alpha > \beta$ (unlike in R)

Algorithm 3 Computation of b

Usage: compute_b(M, K, Tmin, Tmax, DS, delta)

Description: Computation of b - numbering of neurons and k starts at 1

Input: M; integer - number of neurons

Input: K; integer - number of bins

Input: Tmin - minimum time

Input: Tmax - maximum time

Input: DS - DataSpike: matrix with two rows, the first one contains spike values (every spikes in a single row), the second one contains the neuron numbers to identify them in the first one

Input: delta - δ

Output: b - $(1+M*K)$ -by- M matrix

Output: low - array of size Ntot(=length(T)), taking into account the scope

Output: cnt - array of size M, containing $\#^{(r)}$

```
1: T ← DS[1,]                                # first row of DS: all spike values
2: neur ← DS[2,]                              # second row of DS: neuron numbers
3: Ntot ← length(T)                          # total number of spikes
4: A ← K * δ                                # scope
5: b ← matrix(0, nrow=(1+M*K), ncol= M)      # init of b
6: low ← vector(mode='integer', length=Ntot)  # init of low - for the State
7: cnt ← vector(mode='integer', length=M)     # init of cnt - for the algo
8: ilow ← 1
9: eps ← 1.e-12                             # for numerical precision
10: for (i=1:Ntot) do                         # loop over spikes
11:   t ← T[i]; r ← neur[i]
12:   while (|T[ilow] - t| > A) do
13:     ilow ← ilow+1
14:   low[i] ← ilow
15:   if ( $T_{\min} < t \leq T^{\max}$ ) then
16:     cnt[r] ← cnt[r]+1
17:     for (j=ilow:(i-1)) do
18:       if ( $|t - T[j]| < eps$ ) then
19:         break
20:       k ← get_k(t-T[j], delta)
21:       l ← neur[j]
22:       b[(l-1)*K+k+1, r] += 1
23: b[1,] ← cnt                                # 1st line of b
24: return b, low, cnt
```

5 Computation of G

G is a matrix of size $(1 + MK)$ -by- $(1 + MK)$

- First row or first column of G

$$\begin{aligned}
G_{0,l,k} &= \int_{T_{\min}}^{T^{\max}} N_{[t-k\delta, t-(k-1)\delta[}^{(l)} dt \\
&= \int_{T_{\min}}^{T^{\max}} \sum_{\substack{\theta < t, \\ \theta \in \mathcal{N}^{(l)}}} \mathbb{1}_{\mathbb{I}_k}(t - \theta) dt \simeq \int_{T_{\min}}^{T^{\max}} \sum_{\substack{(t-A) \leq \theta < t, \\ \theta \in \mathcal{N}^{(l)}}} \mathbb{1}_{\mathbb{I}_k}(t - \theta) dt \\
&\simeq \int_{T_{\min}}^{T^{\max}} \sum_{\substack{(t-A) \leq \theta < t, \\ \theta \in \mathcal{N}^{(l)}}} \mathbb{1}_{\mathbb{I}_k + \theta}(t) dt \\
G_{0,l,k} &= \int_{T_{\min}}^{T^{\max}} N_{[t-k\delta, t-(k-1)\delta[}^{(l)} dt \simeq \sum_{\substack{\theta \in \mathcal{N}^{(l)}, \\ (T_{\min}-A) \leq \theta < T^{\max}}} (\min(T^{\max}, k\delta + \theta) - \max(T_{\min}, (k-1)\delta + \theta))
\end{aligned}$$

- Inner part of G

$$\begin{aligned}
G_{l_1, l_2, k_1, k_2} &= \int_{T_{\min}}^{T^{\max}} N_{[t-k_1\delta, t-(k_1-1)\delta[}^{(l_1)} N_{[t-k_2\delta, t-(k_2-1)\delta[}^{(l_2)} dt \\
G_{(l_1, k_1), (l_2, k_2)} &= \int_{T_{\min}}^{T^{\max}} \left(\sum_{\substack{\tau \in \mathcal{N}^{(l_1)}, \\ \tau < t}} \mathbb{1}_{\mathbb{I}_{k_1} + \tau}(t) \right) \left(\sum_{\substack{\theta \in \mathcal{N}^{(l_2)}, \\ \theta < t}} \mathbb{1}_{\mathbb{I}_{k_2} + \theta}(t) \right) dt \\
&\simeq \int_{T_{\min}}^{T^{\max}} \left(\sum_{\substack{\tau \in \mathcal{N}^{(l_1)}, \\ t-A \leq \tau < t}} \mathbb{1}_{\mathbb{I}_{k_1} + \tau}(t) \right) \left(\sum_{\substack{\theta \in \mathcal{N}^{(l_2)}, \\ t-A \leq \theta < t}} \mathbb{1}_{\mathbb{I}_{k_2} + \theta}(t) \right) dt \\
&= \sum_{\substack{\tau \in \mathcal{N}^{(l_1)}, \theta \in \mathcal{N}^{(l_2)}, \\ (T_{\min}-A) \leq \tau < T^{\max}, \\ (T_{\min}-A) \leq \theta < T^{\max}}} \int_{T_{\min}}^{T^{\max}} \mathbb{1}_{\mathbb{I}_{k_1} + \tau}(t) \mathbb{1}_{\mathbb{I}_{k_2} + \theta}(t) dt \\
&= \sum_{\substack{\tau \in \mathcal{N}^{(l_1)}, \theta \in \mathcal{N}^{(l_2)}, \\ (T_{\min}-A) \leq \tau < T^{\max}, \\ (T_{\min}-A) \leq \theta < T^{\max}}} \int_{T_{\min}}^{T^{\max}} \mathbb{1}_{(\mathbb{I}_{k_1} + \tau) \cap (\mathbb{I}_{k_2} + \theta) \cap]T_{\min}, T^{\max}]}(t) dt
\end{aligned}$$

Algorithm 4 Computation of G

Usage: compute_G(M, K, Tmin, Tmax, T, neur, delta, A)**Description:** Computation of b - numbering of neurons and k starts at 1**Input:** δ ; delta**Input:** M; integer - number of neurons**Input:** K; integer - number of bins**Input:** Tmin - minimum time**Input:** Tmax - maximum time**Input:** T - flattened array of spike values (every spikes in a single row)**Input:** neur - array of neuron numbers to identify them in T**Input:** delta - size**Input:** A - scope, maximum distance to be taken into account**Output:** b - array of size $(1+M*K)*M$

```
1: G  $\leftarrow$  matrix(0, nrow=(1+M*K), ncol= (1+M*K))           # init of G
2: G[1,1]  $\leftarrow T^{\max} - T_{\min}$ 
3: A  $\leftarrow K * \delta$                                            # scope
4: depart  $\leftarrow$  get_low_index((Tmin - A), T)
5:  $\beta \leftarrow$  get_low_index(Tmax, T) - 1
6: for (i in depart: $\beta$ ) do
7:   ti  $\leftarrow$  T[i];  $l_1 \leftarrow$  neur[i]
8:   for (k in (1:K)) do                                         # 1st row and 1st column of G
9:      $x_1 \leftarrow \min(T^{\max}, ti + k \delta)$ 
10:     $x_2 \leftarrow \max(T_{\min}, ti + (k - 1) \delta)$ 
11:     $dx = x_1 - x_2$ 
12:    if ( $dx > 0$ ) then
13:      G[1,( $l_1-1$ )*K+k+1] += dx
14:      G[( $l_1-1$ )*K+k+1,1] += dx

36:               $G[(l_1-1)*K+k_2+1, (l_1-1)*K+k_1+1] += dx$ 
37: return G

```

6 Computation of d

For d we need the following quantities, μ_2 is a $(1 + MK)$ -by- M matrix. μ_A is a vector of dimension $(1 + MK)$

$$\mu_2^{(r)} = \begin{pmatrix} \dots \\ \int_{T_{\min}}^{T^{\max}} \left(N_{[t-k\delta, t-(k-1)\delta[}^{(l)} \right)^2 dN_t^{(r)} = \int_{T_{\min}}^{T^{\max}} (N_{t-\mathbb{I}_k}^{(l)})^2 dN_t^{(r)} \\ \dots \end{pmatrix}$$

$$\mu_A^{(r)} = \begin{pmatrix} \dots \\ \sup_{t \in]T_{\min}, T^{\max}[} |N_{[t-k\delta, t-(k-1)\delta[}^{(l)}| = \sup_{t \in]T_{\min}, T^{\max}[} |N_{t-\mathbb{I}_k}^{(l)}| \\ \dots \end{pmatrix}$$
